

Evaluation

You can never claim something is working until it's been tested. How did you evaluate your project, so that you can convince yourselves, and others, that you understand the system's performance? The experiments you perform should include hard cases as well as easy cases. The hard cases tell is the limits of what your system can do. You don't have to try show that the system does everything perfectly. That's an impossibility in robotics. The evaluation is to tell us when we would expect the system to work and what it might fail.

Try to repeat experiments as many times as practical, since we usually want to know how a system performs on average. Don't just include cases that worked!

Thinking about how to evaluate a project is something that should be done early, as it helps you to define the scope of the project, i.e. what you hope to achieve and what you don't plan to do.

Conclusion and Future Work

The conclusion is a reflection on what you've done. It is another summary of the work and the results, but this time you can talk about the decisions you made, what went well, what didn't and what you might do differently.

Part of your analysis should include where you would go next with this project. In the case of COMP3431/9431, think of this as suggestions for next year's students who might pick up from where you left off. What advice would you give them?

Acknowledgments (optional)

This section is optional, but if someone helped you in your work or used some equipment, software, etc, you can thank those people here. In a research paper, this is also the place to acknowledge your funding sources, e.g. this research was supported by the Australian Research Council grant DP18123456.
